Quality of Nutrition of Elderly with Different Degrees of Dependency: Elderly Living in Private Homes

Katharina Fritz  Ibrahim Elmadfa
Department of Nutritional Sciences, University of Vienna, Vienna, Austria

Abstract

Background/Aim: To be aware of the influencing factors of healthy aging, several cross-sectional surveys have been carried out among the elderly living in Austria to identify health and lifestyle factors as well as socioeconomic influences that contribute to the nutritional situation. Methods: Information about the health situation was collected by questionnaires. Diet was assessed by both qualitative food frequency questionnaires and 24-hour recalls. Additionally, nutritional status was examined in blood and urine samples using static and functional parameters. Results: The prevalence of overweight (21%, BMI >29) and obesity increased with increasing age up to 65 years; in people older than 65 years an inverse tendency could be observed; as from this age upwards a high prevalence of underweight was found (22%, BMI <24). The consumption of meat and meat products was too high compared to the recommendations. By contrast, the intake of high nutrient density foods was insufficient. On average, the fat intake was around 38% of total energy (%E); that of saturated fatty acids amounted to 20%E; the intake of carbohydrate and fiber was considered as being too low. The intake of folate, vitamin D, calcium, iodine, magnesium and vitamin C was assessed as inadequate. Conclusion: More attention has to be paid to certain micronutrients in order to optimize dietary intake and to sustain health.

Introduction

Nowadays, more and more elderly people become aware of their own health. The behavior or attitude towards life clearly influences a person’s state of health [1]. Nutritional status as well as health status is, among other things, influenced by physiological, psychological, social, and situational factors.

In 1998, the nutritional situation in Austria was documented for the first time in the Austrian Nutrition Report 1998. The Institute of Nutritional Sciences collected data relating to diet, nutrition and lifestyle in selected population groups. In that survey only data on elderly living in nursing homes (NH) were assessed. The nutrition...
monitoring was continued with the Austrian Nutrition Report 2003, where for the first time elderly people living in private households (PH) have been taken into consideration [2].

**Methods**

In the Austrian Study on Nutritional Status (ASNS) in 2003 both elderly people (>55 years; n = 645: 557 women, 88 men) living in nursing homes (n = 233) and in private households (n = 410) were examined. Several methods of data collection were used to investigate health and lifestyle factors as well as diet, nutrition and nutritional behavior; these included a questionnaire, a qualitative food frequency questionnaire, a single 24-hour recall, and blood and urine samples.

Analyses of data in the elderly were done separately for gender, different age groups, and according to the living situation. For differences in energy and nutrient intake between NH and PH, only people older than 65 years (n = 441) were considered.

**Results**

The prevalence of overweight (21%, BMI >29) [4] and obesity rose with increasing age up to 65 years, whereas in people older than 65 years an inverse tendency could be observed. As from this age upwards a high prevalence of underweight was found (22%, BMI <24). The average BMI of the whole sample was 26.7 ± 4.1 within the range of normal weight. Overall, the majority of the sample (57%) was in the normal range of the National Research Council (NRC). According to the living situation, no statistical differences in BMI were found. However, between the age groups the prevalence of underweight was in the 84-year-olds 3 times higher than in the age group of the 55- to 64-year-olds. In general, the body weight tends to decrease with increasing age in healthy people [5].

The highest energy intake was found among men between the ages of 55 and 64 years (9 ± 3.2 MJ). Nevertheless, the average energy intake in every age group was below the recommendations of the D-A-C-H association [6]. The average protein intake in the elderly was, in relation to the total energy intake with 15%E, on the upper limit of the recommendations. In contrast, the fat intake on average was around 38%E. Fat is still a critical nutrient in the Austrian diet with regard to the level of intake and its fatty acid composition. The intake of saturated fatty acid (SFA) was considered to be too high (18–20%E) on account of polyunsaturated fatty acids (5%E). The intake of carbohydrates (45%E) as well as of fiber (20 g/day) did not meet the recommendations.

The average intake of some micronutrients was assessed as inadequate and therefore had to be considered as critical nutrients in the diet of the elderly (fig. 1) as follows: folate, vitamin D, calcium, iodine, magnesium and vitamin C in people older than 84 years.

![Average intake of some micronutrients assessed as inadequate in the Viennese elderly (n = 645).](image-url)
Generally, elderly living at home are better provided with macro- and micronutrients than elderly living in nursing homes. Seniors in PH consumed statistically significantly more fiber and carbohydrates (p < 0.05) than people living in NH, whereas the average intake of protein was significantly lower (p < 0.05) in people living in PH (table 1). The supply of micronutrients of older self-independent men is significantly higher (p < 0.05) than the supply of their contemporaries in the nursing homes. Furthermore, the intake of total water was significantly higher (p < 0.05) in people living in PH. Again among self-dependent elderly, the vitamin D status was significantly higher (p < 0.05). These discovered differences have to be interpreted carefully because of both the low sample size, particularly in men (n = 65), and the method of data collection (24-hour recall).

Analyses on food consumption patterns showed that the intake of high nutrient density foods was mainly insufficient (e.g. vegetables, bread and cereals, milk and milk products), whereas the supply of meat and meat products, sugar and fats was too high according to the recommendations [7].

**Conclusion**

An adequate and balanced diet has a positive influence on the health-promoting lifestyle. As the results show, more attention has to be paid to certain micronutrients in the diet of elderly in order to optimize dietary intake and sustain healthiness.
