Abstract
Objectives: To evaluate the in-patient management of children with acute exacerbation of bronchial asthma and its adherence to international guidelines. Subjects and Methods: Medical records of 100 consecutive admissions for acute exacerbation of asthma to the paediatric wards at Mubarak Al-Kabeer Hospital, Kuwait, from October through December 1999 were retrieved. Data relevant to asthma symptoms, severity, treatment regimens and discharge plan were collected and evaluated. The mean age of patients was 4.3 years, ranging from 2 to 12 years. Admissions totalled 82 males and 18 females, with hospital stays ranging from 1 to 11 days (mean = 2.6 days). Results: There were no fatalities. Reported episodes were severe (17%), moderate (11%) and mild (9%); degree of severity was not documented in 63 cases. Pulse, respiratory rate, colour and use of accessory muscles were not documented in 48, 48, 47 and 63% of the patients, respectively. Arterial blood gas was checked in 16 patients and pulse oximetry in 71. Full blood count, serum urea and electrolytes were obtained in 86 patients and chest radiographs in 76. All patients received nebulized salbutamol. However, some received additional medications: ipratropium bromide (79%), steroids (95%), intravenous aminophylline (5%) and antibiotics (43%). Two children were shifted to an intensive care unit, 1 of whom needed intubation. On discharge, there was no documentation of follow-up arrangements, or prophylactic anti-inflammatory drugs or other medications in 52, 81 and 32 patients, respectively.

Conclusion: Patient management showed deficits, and documentation was inadequate. Areas of particular concern were assessment of patients, unnecessary investigations and use of antibiotics, and lack of post-discharge planning and prophylaxis with steroids. Adherence to the international guidelines was partial.

Introduction
Asthma continues to pose a significant medical problem worldwide, in terms of prevalence, morbidity and mortality [1, 2]. Inadequate management of acute exacerbation carries potential danger to a patient’s life [3]. Poor
Hospital Management of Children with Acute Asthma Exacerbations

documentation and management of asthma in hospitals have been reported by several centres [4–6]. Moreover, the medical care received by patients with exacerbations may vary significantly [7]. For these reasons, the international guidelines for the diagnosis and management of asthma [8] were set forth to assist physicians and patients in deciding appropriate acute as well as long-term management.

In Kuwait, a small desert country, bronchial asthma is a growing problem [9], with evidence of an increasing number of children admitted to hospitals for bronchial asthma [10]. The estimated prevalence of asthma among 13- to 14-year-old children is 16.8% [11]. In an attempt to improve the care of asthmatic children admitted to Mubarak Al-Kabeer Hospital, Kuwait, we introduced a standard protocol based on international guidelines [8] in our wards for the treatment of acute exacerbations of bronchial asthma as well as for long-term management. This initial study evaluates the extent of adherence to these guidelines.

**Results**

Episodes were reported as severe in 17, moderate in 11 and mild in 9 cases. Degree of severity was not documented in 63 patients. The duration of hospital stay was 1–11 days (mean 2.6 days). Two children were shifted to intensive care. Although 1 needed assisted ventilation, there were no fatalities.

Eighty-seven percent of the patients had a past history of asthma, 3% had not, while for 10% this information was not recorded. Equally important, 45% of the patients had been previously admitted for asthma, 13% were not and for 15% no information was recorded. Thirty-six patients received medications previously, 29 did not, and information was missing in 35 cases.

Wheezing was documented in almost all patients, whereas pulse, respiratory rate and colour were not documented in almost 50% (table 1). The majority of children (>75%) were exposed to unnecessary investigations such as chest X-ray and venepuncture, while PEFR was not checked in almost 90% (table 2).
For initial treatment, all patients received at least 4 doses of nebulized salbutamol ranging from 0.01 to 0.03 ml/kg/dose (or 0.05–0.15 mg/kg/dose), and 79% received additional ipratropium bromide at 125–500 μg/dose. Nebulizers, driven by high-flow oxygen, were administered at frequencies shown in table 3. Steroids were prescribed on 95 occasions for a median duration of 3 days (ranging from 2 to 6 days). Eighty-six patients received the steroids in the form of intravenous hydrocortisone and 9 patients as oral prednisolone. The dose ranged between 3 and 10 mg/kg/day for hydrocortisone (median 5.5 mg/kg) and 1–2 mg/kg/day prednisolone (median 1.7 mg/kg). Intravenous aminophylline was given to 5 patients: all had severe exacerbation of their asthma and 2 needed assisted ventilation. Oxygen via mask was received by 36 patients for a period of 3–28 h (mean 6.5) and antibiotics were prescribed for 43% of the admissions. Table 4 is a summary of action probably taken but not documented before discharge of these patients.

### Discussion

The use of asthma assessment and management protocols helps overcome many of the clinical problems associated with the management of acute asthma. Their implementation also serves an educational function when used by junior staff members who are usually delegated responsibility for the care of asthmatic children. Results of our study show multiple problems in conforming to the standard care delineated in the standard protocol. In addition, documentation was poor and management ineffective.

The presence of wheezing was the single most recorded observation (98%). However, essential data such as the degree of accessory muscle use, pulse, respiratory rate and colour were not recorded in almost 50% of cases (table 1). PEFR, a simple test bearing directly on the severity of the attack, was not recorded in almost 90% of the cases, and overall assessment of the severity of attack was not recorded in 63% of the children. This raises considerable concern as to the basis of a management plan, which is determined by the severity of an attack followed by appropriate therapy as recommended [8, 12]. Frequent or continuous nebulization of β2-agonists is required in acute severe asthma as recommended by the recent international guidelines. Eighty percent of our patients received frequent (2-hourly, hourly and continuous) nebulization of β2-agonists, which suggests that 80% of episodes were severe as opposed to the 17% that were recorded. In addition, 79% received additional ipratropium bromide (table 3), which also suggests that attacks were perceived as severe by admitting staff. In all cases, the actual doses prescribed per nebulization were acceptable on all occasions. The argument that severity could have been assessed and not documented demonstrates inadequate management
strategy, which could carry additional risk of mismanage-
ment because it failed to provide baseline data necessary
for optimizing therapy. In addition, documentation is a
mandatory requirement for continuing care by medical
personnel working on different shifts and teams.

Antibiotics have no role in treating acute attacks of
asthma, being indicated only for patients who also have
bacterial infection such as sinusitis or pneumonia [12].
Forty-three percent of our patients received antibiotics, in
most cases intravenously and almost all without justifica-
tion: only 1 patient had associated pneumonia (Mycoplas-
ma pneumoniae) and 2 otitis media. Overprescription of
antibiotics is not unusual in this part of the world. A pre-
vious study [13] in this hospital showed that the majority
of children with viral respiratory tract infections received
antibiotics. However, this may be a major problem world-
wide.

It has been shown that the incidence of radiographic
abnormalities in asthma is low, abnormalities are minor
and usually do not substantially influence treatment [14].
In acute asthma, chest X-rays are essentially used to
detect complications such as pneumothorax or atelectasis
and hardly add anything if routinely performed [15]. In
this study, 76% of children had a chest radiograph per-
formed on admission of whom 23 had previous ones
despite the fact that only 17% were reported as having
severe asthmatic episodes. In our hospital, the use of anti-
biotics and chest X-rays was left to the discretion of the
treating doctor. Unnecessary chest X-rays in acute asthma
have been reported from developed [14–16] as well as
developing countries [17]. This practice indicates unnec-
essary exposure of children to radiation as well as unnec-
essary increase in cost.

Salbutamol and steroids may cause hypokalaemia;
thus, monitoring of potassium concentration is desirable
when these drugs are frequently used as in severe acute
exacerbations [18]. The overwhelming majority of our
patients had an order for serum urea and electrolytes on
admission, rather than after they had received repeated
doses of salbutamol and hydrocortisone. Simultaneously,
a complete blood count was carried out on the same chil-
dren. This is not part of recommended guidelines, as com-
plete blood count may only be of some help if concomi-
tant bacterial infection is likely. Likewise, serum potas-
sium should routinely be selectively and appropriately
watched for, not routinely administered.

Almost 95% of patients received corticosteroids during
acute attack, consistent with the guidelines [8]. However,
our findings showed no adherence to these recommen-
dations as the overwhelming majority of the patients (ta-
ble 4) were not on prophylactic anti-inflammatory ther-
apy as recommended in all guidelines [8, 19–21]. Anti-
flammatory therapy is important in planning long-term
management. Failure of adherence to anti-inflammatory
medications for treatment of chronic disease may be
responsible in part for continued disease activity.

In this first documentation of the standard of in-
patient care of asthmatic children with acute exacerbation
in Kuwait, our observations are more negative than others
[4, 6], but very similar to and slightly better than others
[17]. In-hospital treatment with asthma medications was
appropriate. However, documentation of assessment of
asthma severity was inadequate, patients were unneces-
sarily exposed to radiation and venepuncture and re-
ceived unnecessary antibiotics, and planning on discharge
was missing and patients were deprived of the benefit of
prophylaxis with inhaled steroids.

**Conclusion**

The provision of the management guidelines in this
hospital has positively influenced the emphasis on acute
treatment (increased use of corticosteroids, continuous
administration of nebulized salbutamol, and more utiliza-
tion of pulse oximetry) but not documentation or long-
term plans. It is imperative that these aspects of manage-
ment are addressed and closer compliance reinforced.
